

The operator lens is HUB-attributable, not cell-attributable: the weekly fixed bill is sized by the hub's peak day, so what one area contributes to it depends on when the rest of the hub peaks. Panels (c)-(e) therefore aggregate the per-area attribution to the hub before taking a saving. Panels (d) and (f): the small-hub buckets hold DHL cells only, because DHL runs the only multi-depot network in the case study (16 hubs; every other LSP has a single depot). Hub size and carrier identity are confounded there, so those two panels are within-DHL statements, not general laws. Cost model: 189.15 EUR/vehicle-day + 0.3864 EUR/km + 36 EUR/route-hour (VROOM per_hour default).
