

Grid v6. In (a) the routing-optimal plan (stage 1) is solid, the operator-polished plan (stage 2) dashed; the curve is the provider mean of the LSPs' mean delivery days.

Express quantities in (b1)/(b3) come from the stage-2 cost decomposition; the penalty mass in (b2) and the saving in (b3)/(c) are stage 1. Express tour = parcels of non-willing customers on days without a regular tour, bundled at the depot; in (b3) the saving jumps at $\theta = 1$, where that component disappears. Panel (c): all 312 cells at $P = 0$; a two-day plan's penalty is $\approx P \times 1$ waiting day per parcel.
